Abstract

The article is devoted to the origin of horse riding and the developmental stages of the riding harness used by the ancient nomads in Central Asia. Three stages stand out in the domestication of the horse as determined by archaeological materials. The Early Stage, (middle to the end of the second millennium BC) is the development of the chariot harness. The second, the Arzhan Stage (11th–7th centuries BC) is the Early Scythian period in which bridle bits and cheekpieces, manufactured in bronze became varied. During this time the funeral rite includes horse burials. During the third stage, the Pazyryk (7th–4th centuries BC), the saddle and harness become richer and more complex. Images carved in rock (petroglyphs) reflects the main stages of harness development.

Keywords

Early Nomads, origin, horse riding, riding harnesses, Central Asia

Introduction

The snowy steppes of Eastern Europe required that animals be kept in stalls and given fodder during the winter (Rudenko 1961). In contrast, the most favorable geographical conditions for the development of mobile forms of cattlebreeding (i.e., year-round pasturing) lay in the territory which stretched from the Ural Mountains eastward to Mongolia. Attempts by some scientists (Anthony 1986; Zaibert, et al. 1990, etc.) to interpret bone articles from Eneolithic sites in Eastern Europe and northern Kazakhstan (i.e., Derievka, Tjubek, Botai, etc.) as cheekpieces, and accordingly, to extrapolate the development of horseback riding from this information, is not absolutely convincing for a number of archaeological reasons (Bokovenko 1997). In addition, their theories have been developed in the absence of reliable osteological data (Kosintsev 1999; Levine 1999).

It was only at the end of the Bronze Age that a sporadic development in the steppe cultures occurred in which horseback riding was mastered—and this was probably by shepherds. It is during this time that finds of bone and rod-shaped cheekpieces with various modifications are noted, as well as being illustrated in numerous rock drawings (Bokovenko 1979; 1986). It was only at the beginning of the first millennium BC—in connection with significant progress in horsebreeding and the development of a more reliable type of bronze bridle—that for the first time an early Scythian-type nomadic society depicted a horse rider in the form of a centaur.

Development of horse harnessing

The lifestyles of the many nomadic cultures were varied. They had generically evolved from the earlier Bronze Age cultures in which vehicles and battle-chariots existed. The optimum lifestyle involved vertical, or year-round migrations of complex herds, capable of extracting fodder during the winter from beneath the snow. Convenient and easily portable dwellings and utensils were also invented. Thus, for the first time, a specialized horse rider with armaments came into being. Units, comprising this new cultural type, rapidly became assimilated into steppe cultures from the Ural Mountains to Mongolia. In these locales, the breeding of various types of horses and sheep (Witt 1952; Tsalkin1952) fostered the further development and integration of three cultural blocks, i.e., cattlebreeding, agriculture and craftworking. In addition, leaders, a military-priestly aristocracy, and other social strata were developed. Nomadic societies, in turn, required complex religious systems that substantiated and solidified these statuses; this was achieved through funeral rites, definitive signs that became symbolic of the horse rider, arms, and art—such as the examples discovered during excavations at Arzhan, Besshatyr, Pazyryk, Salbyk, Issyk, etc.

Analyses of the archaeological materials provides evidence for the creation of Central Asian nomadic riding bridles that further stimulated the development of various armaments and costumes. The armed horse rider was created from this system. Some stages of this process are illustrated in Figures 1 and 2 and listed below.

(1) The earliest stage of the development of horse riding equipment occurred during the Bronze Age (middle to the end of the second millennium BC). At first, the primitive horse bridle consisted of a plaque cheekpiece with prongs on one side; this was followed by the development of bar cheekpieces, carved from horn, with three holes and strap bits that were not firmly fixed. These types of bridles were not particularly reliable for controlling a horse, and probably were used only on draught animals. It is possible, however, that they may have been used...
incidentally for riding purposes, for example, by shepherds. This bridle type was widespread in the Eurasian steppes from Hungary to Mongolia. Chariots burials and the formation of a nomadic aristocracy are known from this period.

(2) The initial stage of the Early Nomads (Scythian-type Culture) at Arzhan, 9th–7th centuries BC, is characterized by the mass manufacturing in bronze of the basic elements of the bridle. At this time there is a significant qualitative change. At first, bronze cheekpieces simulate the types that were made in horn, then metal allowed artisans to create essentially new forms. The greatest variation of bronze bits (seven types), and cheekpieces (eleven types) for all periods of nomadic life, may be observed during this time. The basic bridle bit form and the quantity of external terminals became modified (Fig. 2), and stirrup-shaped bits prevailed in Kazakhstan and the Sayan-Altai region (Aksheev 1973; Vishnevskaya 1973; Gryaznov 1984; Bokovenko 1986; Itina and Yablonsky 1997; Kirushin and Tishkin 1997). Cheekpieces, generally with up to three holes, were of the most different and difficult types, and were designed to be fastened to the bits with special small straps.

In the Sayan-Altai, among the available materials from early Scythian sites that have been radiocarbon dated (Marsadolov 1997), no less than 37 bridle variants have been recorded; this finding testifies to the intensive quest by the nomads for the most reliable and convenient forms of horse equipment (Bokovenko 1986). The improvement of all the harnessing is combined with the localization of specific types of bits and cheekpieces, such as the types from the Minusinsk Basin, Tuva, and the Altai. The most favorable forms were replicated, while others become obsolete.

Phalera, breast ornamentation for horses, is found manufactured in primitive horn (as plaques) as well as being fashioned from bronze into magnificent plaques with beautiful bas relief of a coiled predator—the snow leopard—such as the example recovered from the Arzhan Kurgan (Figs. 3, 4). Due to the mobility of the nomads, and the dynamics of intercultural contacts, new types of horse harnesses were quickly distributed, while the most imperfect gradually “disappeared” or entered into a “struggle,” with traditional local forms.

(3) Beginning at the end of the 7th century BC, the new Pazyryk Style is identified with a wide distribution from Mongolia to Hungary. At this time an essentially new bridle design came to the fore, in which cheekpieces were no longer snugly fastened to bits with straps as had been the case in previous times; straps were now inserted into extended ring-shaped terminals. From this time onwards, cheekpieces varied little in form although there was an evolution in the style of terminal which saw an increased use of those with two holes. Cheekpieces with ring terminals obviously improved the manageability of the horse, and other types of bits and cheekpieces were essentially not used since this bridle design continued until the Middle Ages. Thus, an efficient bridle was developed, saddles were simple as illustrated at Pazyryk, and although metal stirrups had not yet been invented, stirrups were probably made from leather straps.

Iconography and semantics of horses in burials
At Pazyryk I, the remains of ten gold-colored horses were discovered. The highest quality of these, based on the judgement of Gryaznov (1950: 167), belonged to the Central Asian breed that was glorified in antiquity; today the descendants of these horses are the famous modern Turkmen horses (Gryaznov 1950: 167). The remaining horses represented crossbreeding of the Central Asian breed with local small, but strong and hardy horses. It is interesting to note, that each horse at Pazyryk had a different mark on its ear that probably represented different ownership and, the horses most likely represented “gifts of grief” from subordinate patrimonial elders to the buried chieftain.

The horses found in all of the kurgans were buried with magnificent harnesses; their manes and even eyebrows had been carefully trimmed. Usually two horses were decorated with particularly rich finery, and it would seem probable that these animals had belonged specifically to the chieftain. The head of each horse was decorated with a mask representing a horned tiger, while the tail was dressed with a cover. One horse wore a tiger mask with huge stag horns made from heavy leather. The saddles were decorated with hanging images of fish (Fig. 5).

Semantically, the analyses of these magnificent horse harnesses are complex and are connected to the creation at this time of Indo-Iranian mythology and the introduction of shamanism. It is clear that the ancient shamans created harness compositions on the basis of definite mythologies, which are reflected in the position of the sacrificed horses within the burials of the military aristocracy. Images correspond to the Animal Style and also are represented in a wide range of colors. Herewith, we can conditionally track, using iconography, the three worlds of the nomads:

(1) The Upper World–head and neck of a horse (stag’s mask, birds).

(2) The Regular World–chest of a horse; pommel; and saddle pillow (where the person sat), covered with the struggle of non-predators being attacked by predators (ungulates and felines as a signature stamp).

(3) The Lower World–fish portrayed hanging down from a saddle and defeated animals.

The combat scenes are interpreted in different manners by some scholars: (a) tribal struggles (Gryaznov 1950); (b) forces of goods and evil, life and death (Artamonov 1973) and; (c) bright sky contrasted with darkness, earth, change of seasons, etc. As a whole, the images testify to the existence of elements within the local religious belief systems that subsequently rendered significant influences on the spiritual development of many Asian peoples.

Conclusions
The developments apparent among the horse equipment of Central Asia reveal a clear continuity of the bridle components of the Bronze Age through to the Early Scythian period. This is illustrated, for instance, in rock art (Fig. 6). The search for the
optimal solutions resulted in harnessing that became a canonical type of extreme significance to the nomads. Moreover, a specific type of horse harnessing, as noted in the royal mounds at Arzhan where horses were decorated with boar’s tusks, displayed solar symbols and snow leopards as predators, etc.

The main culturo-historical value may therefore be obtained when analyzing the morphological characteristics of Central Asian horse harnessing at the beginning of the first millennium BC. A local funeral tradition surfaced in which the appearance of a horse cult was brilliantly exhibited in the nomadic art of the Sayan-Altai region. A dominant role was played by stag and sun images that generally correspond to written sources relating to the Saka and Massagetae. Therefore, it is apparent that this style originated in an area that was much further to the east than previously has been recognized.

Thanks to the horse, nomadic activity was increased considerably and allowed comprehensive trade relations to come to develop. Cultural communications became diversified, interacting with the tribes of the taiga (forest) on the north; and in the south with the civilizations of Central Asian, India, and urban China. Nevertheless, cultural impulses and migrations to the west were in force in the late second-early first millennia BC (Jettmar 1964; Terenozhkin 1976; Ilinskaya and Terenozhkin 1983; Klokho and Murzin 1987; Kossak 1987; Bokovenko 1989a; 1989b). Typological analyses of the basic components of nomadic culture indicate that there were difficult processes and areas of progress in migrations as well as with concepts and artifacts. At first, the movements of the Scythians, the Saka, the Massagetae, and the Sarmatians, largely changed the ethnic and cultural situation in Asia and Europe. Later the Hsiung nu and the Huns became responsible for these changes. These movements also created the necessary preconditions for the development of trade routes between the various regions.
